# `Kanata' 1.5-m Optical Telescope

# Higashi-Hiroshima Observatory

- Found in 2006; operated by Hiroshima University
- Only 25 min by car from campus (503m above sea level)
- ~40% observable nights
- Better seeing condition (median FWHM ~1.2 arcsec)
- Sky brightness  $R=19-20$  mag/arcsec<sup>2</sup> in dark nights

# Higashi-Hiroshima Observatory: Aim

Multi-wavelength and/or Multi-band study for variable, transient objects

**Gamma-ray, X-ray and Optical/NIR Observations**

GRB, XRB, AGN, etc

1.5m Optical/NIR telescope, Kanata (2006-)

Gamma-ray satellite (Fermi 2008-)

X-ray satellite (Suzaku 2005-, Astro-H 2016-)

# Telescope and Instruments

Nasmyth focus#2

## High Speed-readout spectrograph

FoV: 2.3' × 2.3'

Wavelength res.:  $R = \lambda/\Delta\lambda =$   
9-70 (400-800nm) ,  
150 (430-690nm)

~30 frames/sec

Cassegrain focus

Nasmyth focus#1

## HOWPoI 2009-

Opt Imaging: FoV 15'Φ

Opt ImagPol: One-shot type

Spec:  $R \sim 400$  (400-1050nm)

We-Do-Wo type Wollaston

**One-shot polarimetry'**

**is available** --- Unique potential for quickly-variable object like GRB afterglows

## 'Kanata' Telescope

- Successor of IR simulator of Subaru telescope
- 1.5mΦ main mirror
- Azimuth rotation speed : 5° /sec, 2-4 times faster than normal 1-m size telescopes. (merit in high-response observation (e.g. GRBs))

## HONIR : 2012-

1 Optical band + 1 (future 2) NIR band (simultaneous)

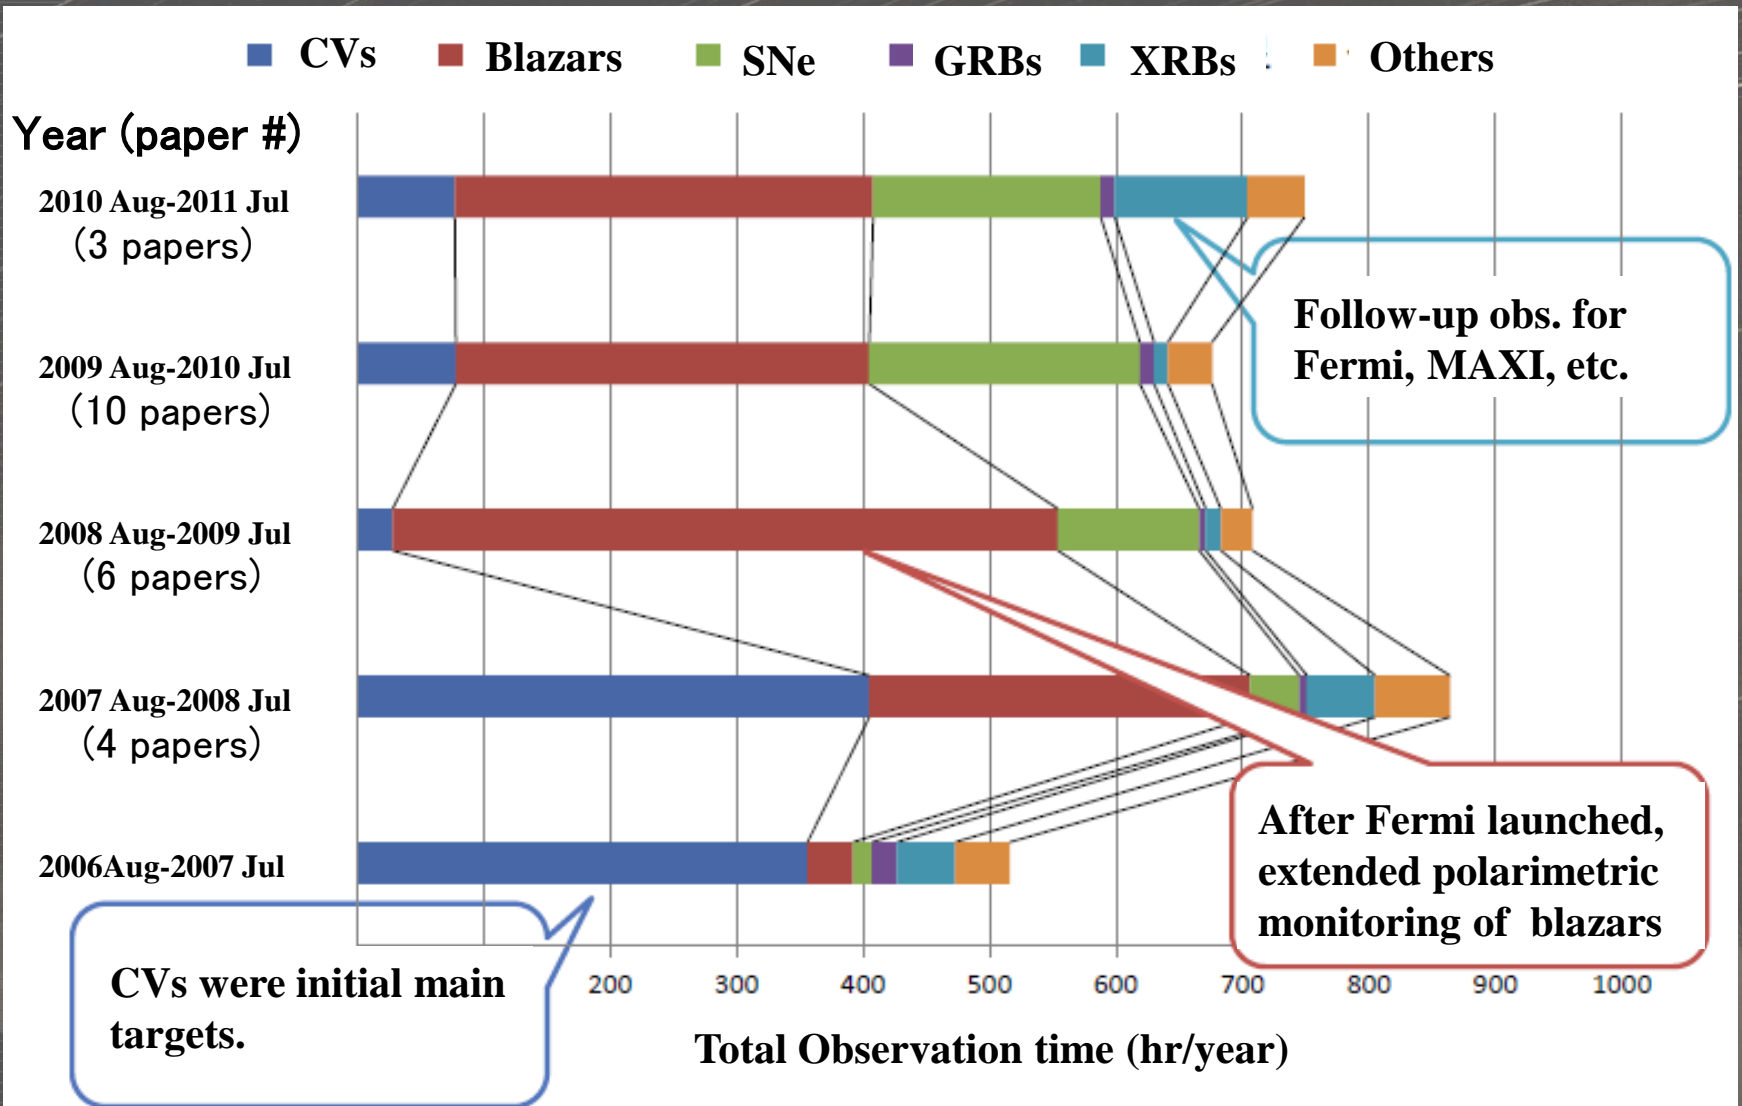

Opt+NIR Imaging: FoV 10' × 10'

Opt+NIR Spec:  $R \sim 400-500$

Opt+NIR ImagPol/SpecPol

**Maximizing information by single observation**

A few Campaign Observation in a year

# Strategy of Kanata Telescope

# Discrimination from other telescopes

- Transient phenomena
  - Requiring high response system and/or extended observations (being hard for large telescopes)
- Multi-wavelength
  - Coordinated with X/Gamma-ray observations supported by high-energy (and theoretical) people.
- Multi-mode
  - Simultaneous Opt/NIR observation including polarimetry and spectroscopy, maximizing information gaining from a single observation.

## Comment for multi-wavelength observation

- There are large differences in observing technique and conditions between Opt/NIR and X/Gamma-ray regimes.
- Special skill is required for planning an effective multi-wavelength collaborative study.
- For long-lasting collaborative study, daily cooperation (, mutual understanding, and interdependence, ...) will be necessary.
- Our group may luckily satisfy it, because it has established supposing daily education and collaboration in a single unit.

## Comment for multi-mode observation

- Polarimetry has been focused in our instrumentation and observation.
- Generally, 'polarization of light' is minor subject in astronomy (although I disagree with it) and optical instruments having capability of polarimetry is still rare.
- It is quite rare that a polarimeter is always attached to telescope (that is, polarimetry is capable every night at the telescope), even among worldwide 1–2-m class small telescopes.

Opt+NIR Spec:  $R \sim 400-500$

Opt+NIR ImagPol/SpecPol

Maximizing information by single observation

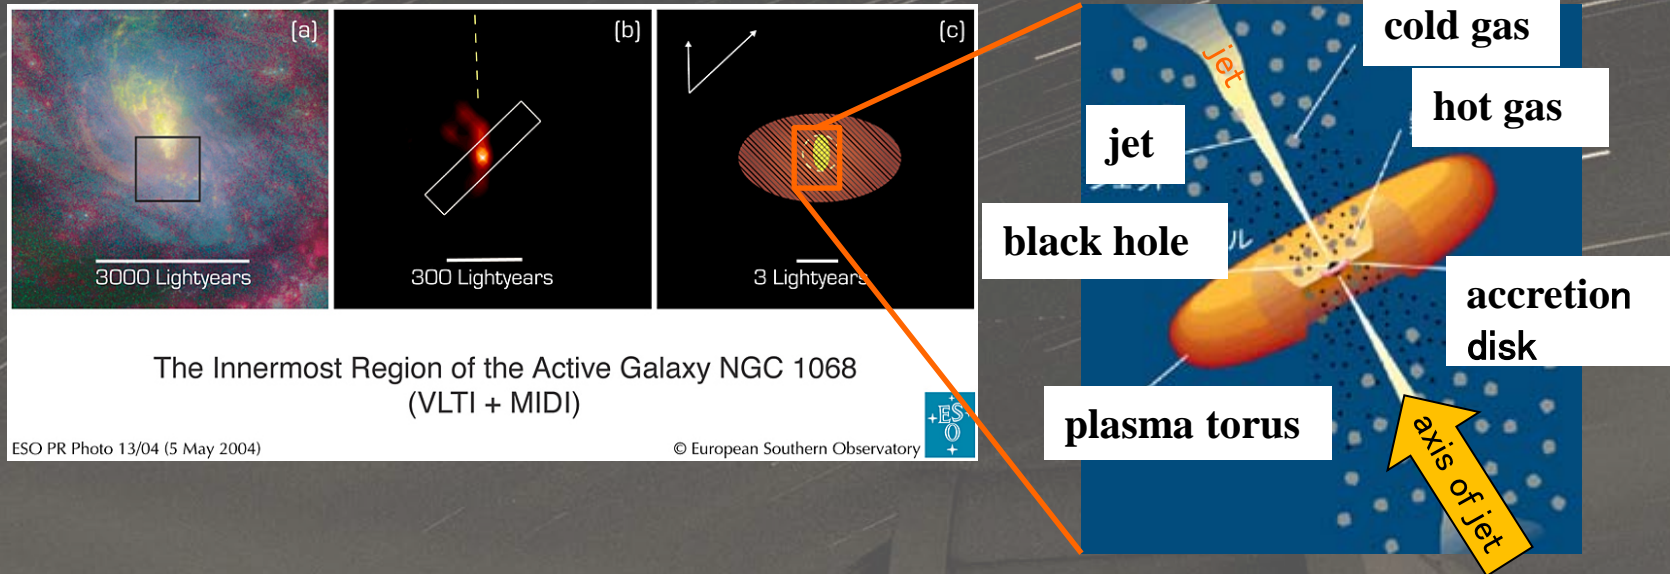

*Kanata tel. is quite unique facility*

# Multi-wavelength Observation Sample 1: Blazars and related objects

# Blazars

Blazars are believed to be AGN seen along the jet axis.  
→ Synchrotron radiation would dominate the flux at  
IR/optical wavelengths

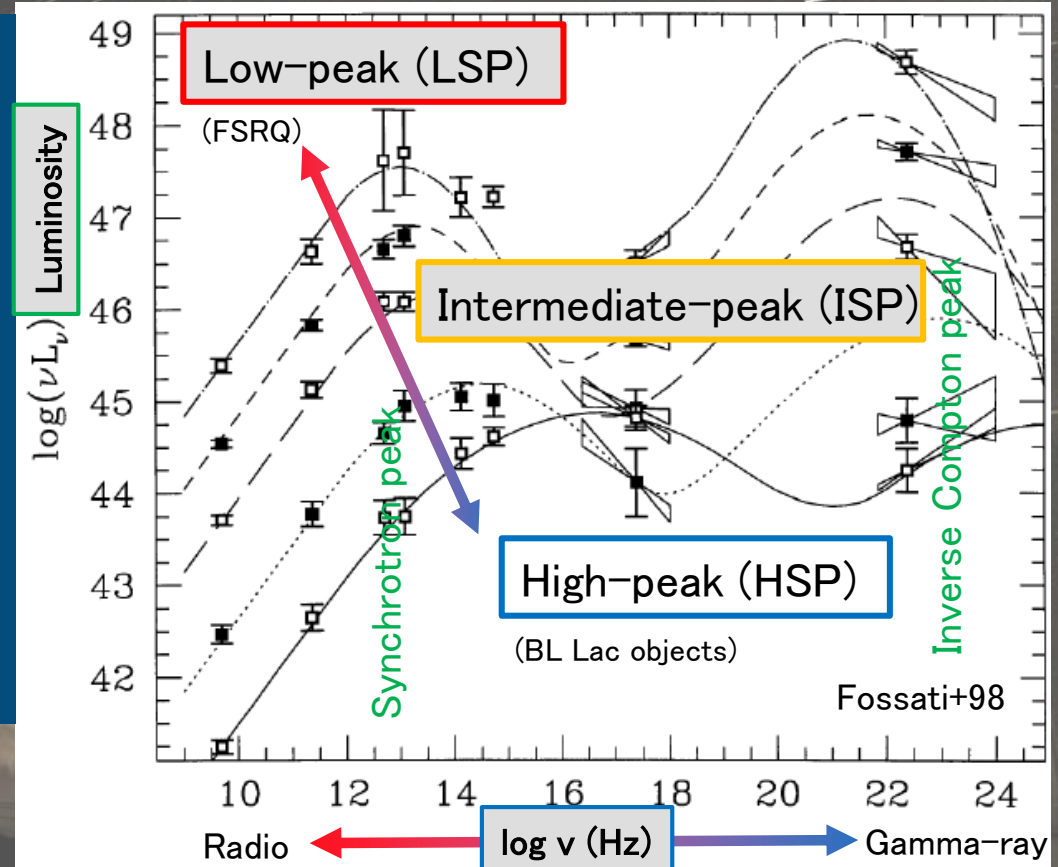

# SED of Blazars

Relativistic beaming;  
brightened by  $\delta^4 \sim 10,000$  times

Emission from the jet dominates  
from radio through gamma-ray;  
rapid and large amplitude variability  
and strongly polarized light

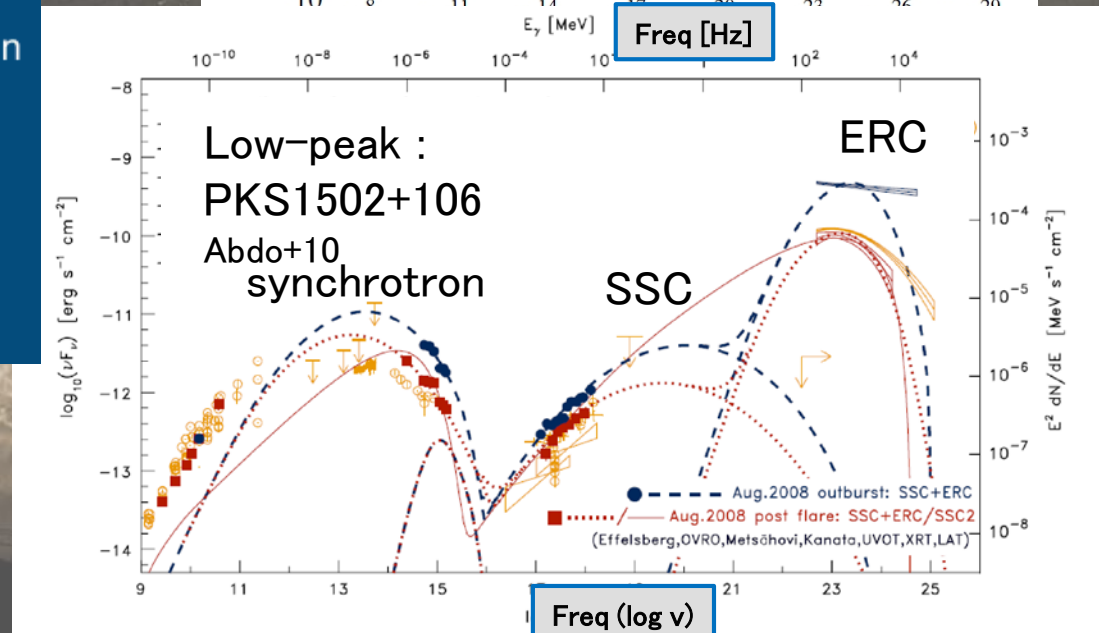

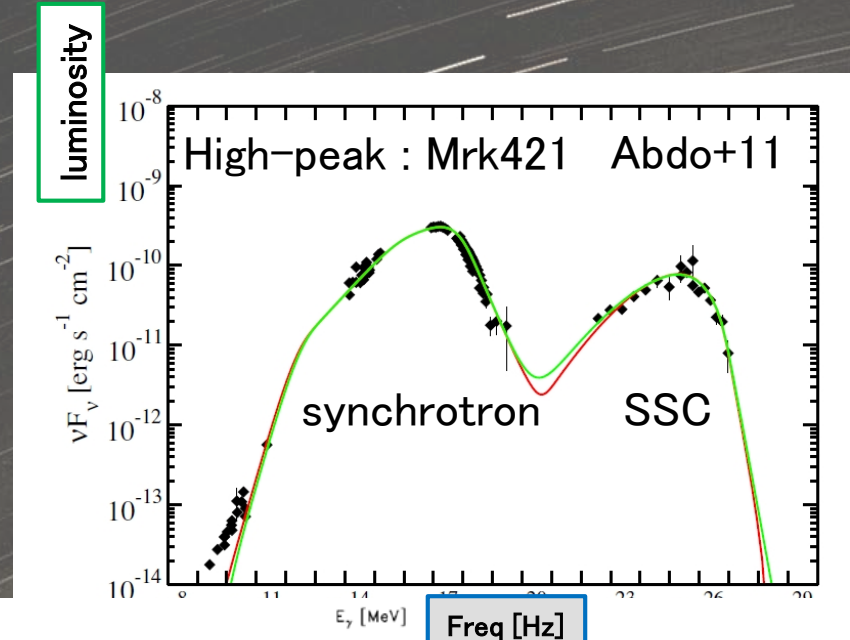

# Emission model of high energy part

Synchrotron – Self Compton (SSC)  
 External Radiation Compton (ERC)

Emission at GeV regime  
 High-peak : SSC  
 Low-peak : ERC

# Kanata Blazar Photo-Polarimetry Campaign

We performed polarimetric campaign with Kanata telescope and a simultaneous optical and NIR instrument, as a joint observation with *Fermi* Gamma-ray satellite in 2008–2010.

42 blazars (13 FSRQs, 8 LSPs, 9 ISPs, and 12 HSPs; the classification based on Abdo et al. 2010) are monitored in V, J, and Ks-band.

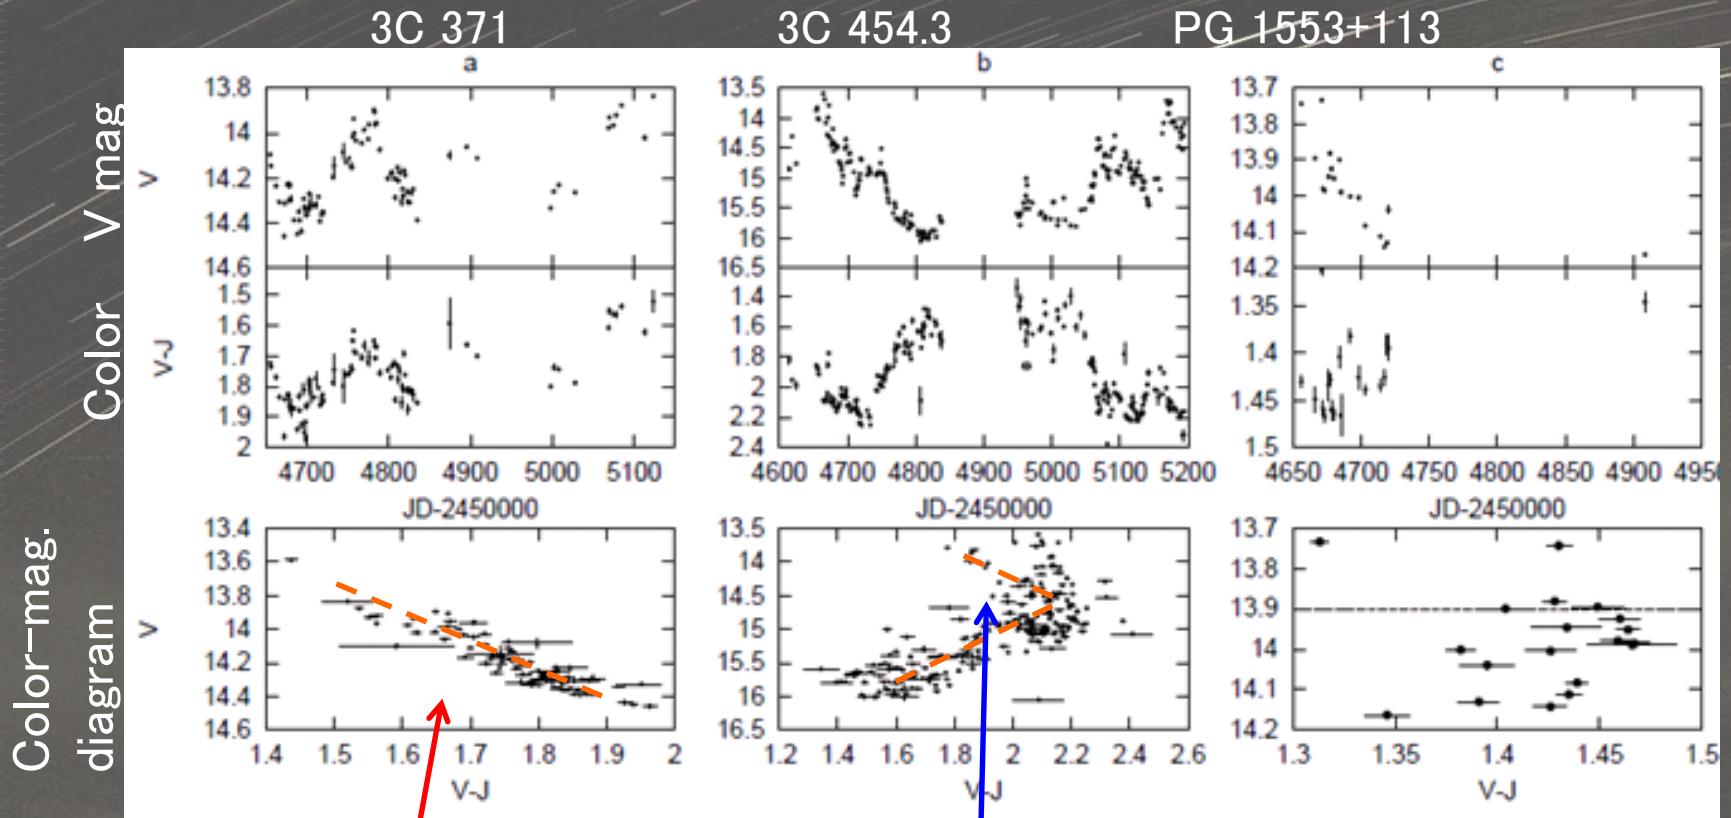

**Most comprehensive polarimetric data set obtained.**

Ikejiri et al. 2011

**Coming soon!**

- Bright in GeV gamma-ray
- Observable with Kanata telescope
- Flares have been observed

# Multi-wavelength Observation Sample 2: X-ray binary; Micro quasars

# X-ray binary

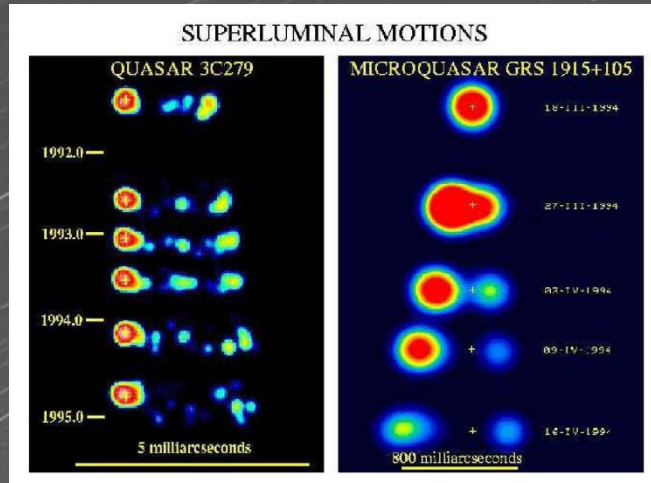

Binary including BH or NS

XTE J1118+480; Markoff et al (2001)

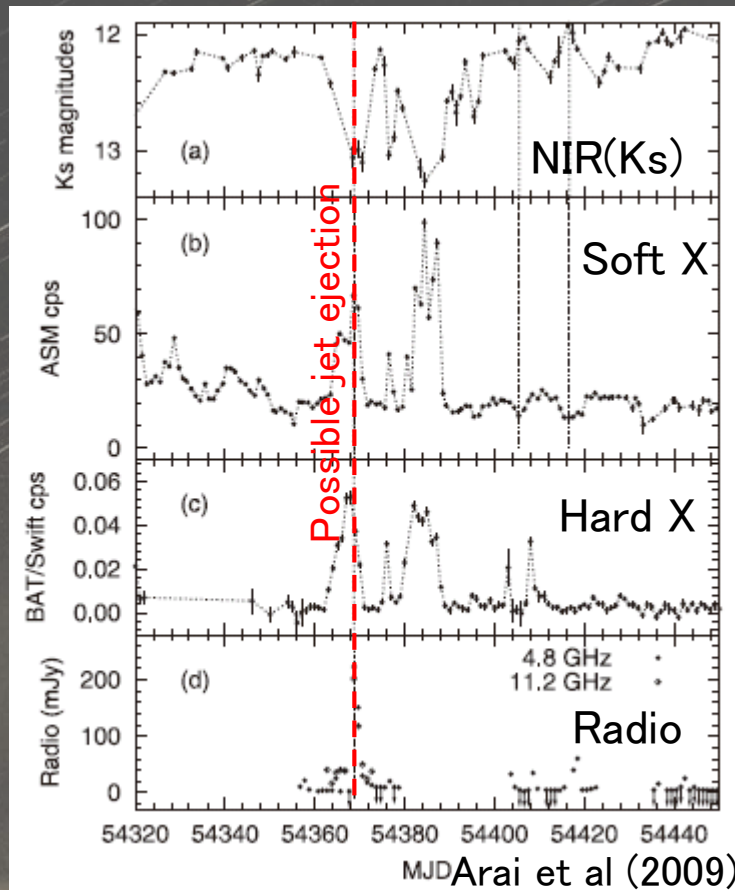

- It has been claimed that NIR light is produced by jet. (Most X-ray binaries locate near the milky way, and the optical light is heavily absorbed, but NIR light is much less absorbed.)
- Thus, jet can be probed by NIR observation (as well as X-ray and radio observations)

# GRS 1915+015 as 'microquasar'

- Superluminal motion in radio (VLBI)
  - High-velocity jet → Called as microquasar
- BH mass  $14 \pm 4 M_{\odot}$  from NIR spectroscopic period (Greiner et al. 2001)
- A time-sequential flare among X-ray, NIR and radio wavelengths is found, explained by disk-jet model (Mirabel et al. 1998)
- But, the observational material for accretion and jet physics is still poor.

# Anti-correlation in X-ray and NIR

NIR photometric monitoring.  
X-ray hardness ratio suggests  
this binary is in soft state at  
MJD 54320–54570.  
Around MJD 54370, X-ray and  
radio flare appeared  
→ jet ejection  
In contrast, NIR flux decreased.  
(Time lag < 1d)

This NIR – X/radio anti-correlation continued during its  
soft state (~250 d).

# What does the anti-correlation indicate?

Arai et al (2009)

- NIR flux becomes redder at flare.  
This suggests that the jet synchrotron component is significant at flare, but thermal emission from hot accretion disk dominates NIR flux normally.
- Why does NIR flux decrease at jet ejection?  
Accretion disk disappeared temporally?  
Coronal disk wind hides the disk in NIR?  
Future NIR spectroscopy and/or polarimetry will give another insight.

# Multi-wavelength Observation Sample 3: Gamma-ray bursts and their afterglows

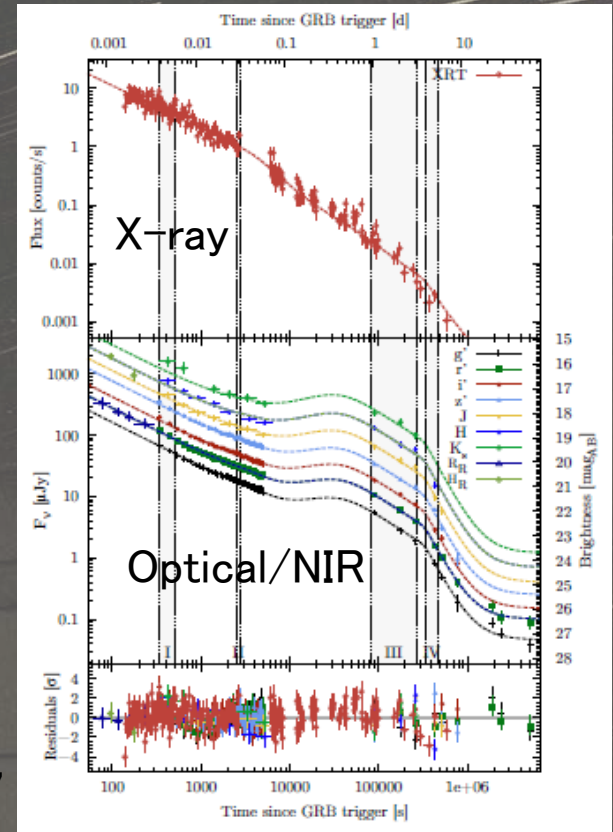

# Afterglow of GRBs

A considerable fraction of GRBs (~30%) show afterglows in optical wavelengths.

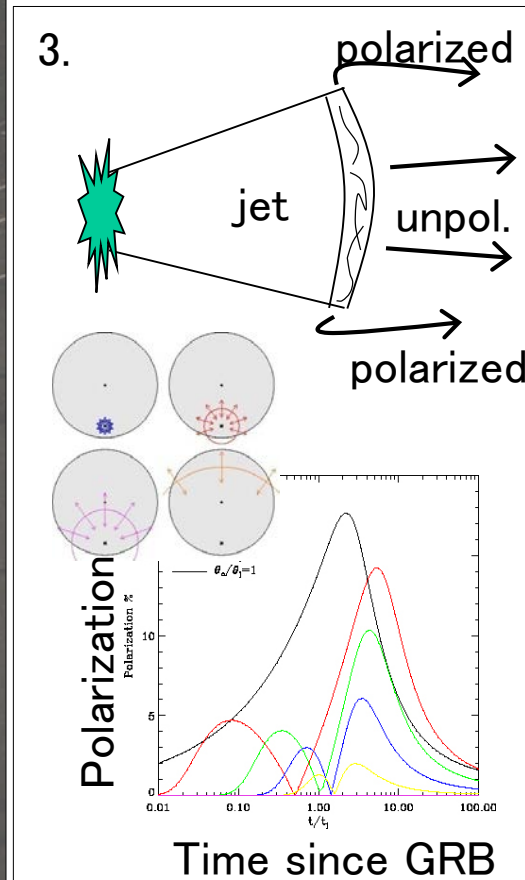

They are explained by synchrotron radiation originated in an external shock region where the relativistic jet interacts with circumstellar matter.

080413B Filgas+ 2011

# Expected geometry of magnetism and polarization

1. **Totally random orientation of magnetism.**  
 → Null polarization
2. **Combination of coherent patches (scale length  $\sim c\tau$ ).** Within each patch, the magnetic field is ordered. Normal jet may have  $\sim 50$  patches.  
 → Constant polarization of  $\sim 10\%$  ( $=70\%/\sqrt{N}$ )  
 (e.g., Gruzinov & Waxman 1999)
3. **Axi-symmetric polarization pattern due to compressed, tangled magnetic field, coupled with relativistic 'beaming' and 'occultation' of emitting region.**  
 → Variable polarization of  $p=0-10\%$  from oblique line of sight (e.g, Sari+ 1999; Rossi+ 2004)
4. **Large scale ordered-magnetic field in (not hydrodynamic jet, but) Poynting-flux dominated jet** (e.g, Lyutikov+ 2003)  
 → Large polarization (up to  $\sim 50\%$ )

Rossi+ 04

# List of Kanata optical polarimetry for GRBs

	GRB trigger t1	GCN receive t2	Expos. start t3	t3-t1 (s)	t3-t2 (s)	Polarized?
GRB 091208B	9:49:58	9:50:24	9:52:27	149	123	Yes
GRB 111228A	15:44:43	15:45:33	15:47:25	162	112	Yes
GRB 121011A	11:15:30	11:16:09	11:17:02	92	53	No
GRB 130427A	7:47:57	7:49:15	11:40:26	14027	13949	No
GRB 130505A	8:22:28	8:22:51	10:46:08	8643	8620	No
GRB 140629A	14:17:30	14:17:46	14:18:43	73	57	No

We have the record of earliest observation ( $\lesssim 100$ s after gamma-ray trigger) for GRB afterglow in polarimetry (091208B, 121011A, 140629A).

# GRB 111228A ( $z=0.714$ )

Takaki, Toma, KK+, submitted

Optical afterglow shows significant temporal polarization change.

**GRB 111228A: Strongly polarized**

Katsutoshi Takaki will give a talk on the study of this GRB afterglow on third day of this GRB conference.

# GRB 140629A ( $z=2.3$ )

$$T_{90} (15\text{--}350\text{keV}) = 75.6 \pm 12.7 \text{ sec}$$

$$\text{Galactic } A_V = 0.022 ; \text{ upper-limit } p_{MW} \sim 0.07\%$$

Polarimetry began at  $T_0 + 73$  s  
(22 s in rest frame)

The record of earliest polarimetry ever!

$$p = 1.8 \pm 1.1 \% \text{ at } T_0 + 73 \text{ s to } 185 \text{ s}$$

$$p = 1.5 \pm 1.8 \% \text{ at } T_0 + 198 \text{ s to } 436 \text{ s}$$

$$p = 2.8 \pm 6.4 \% \text{ at } T_0 + 7456 \text{ s to } 8618 \text{ s}$$

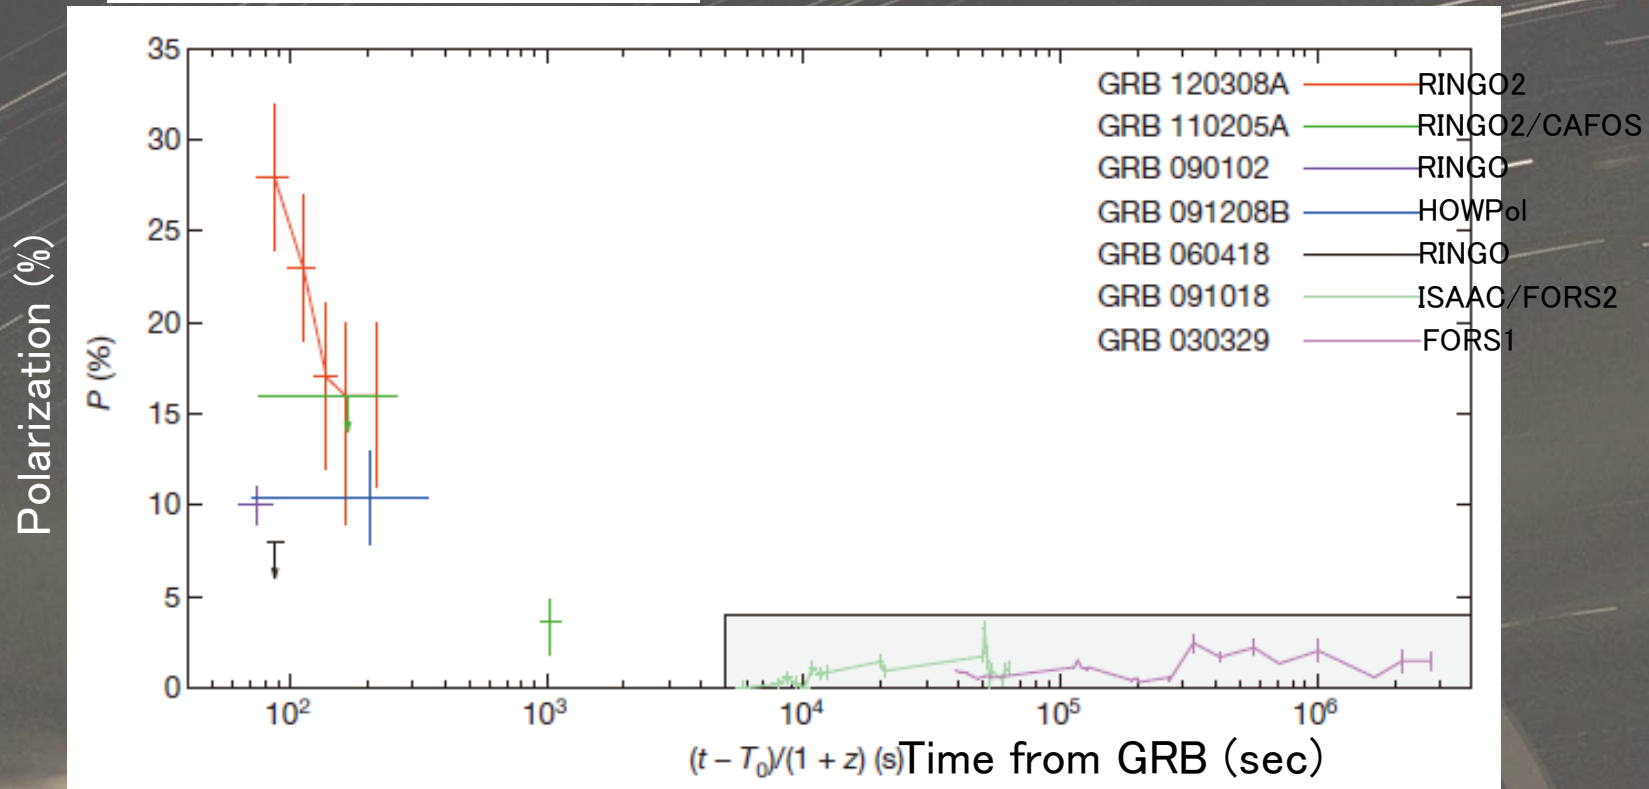

GRB 140629A: Unpolarized (or only weakly polarized)

# Other early afterglow polarimetry

Mundell+ (2013), Nature

Earliest afterglow is generally strongly polarized?

# Other early afterglow polarimetry w/ HOWPoI data

Mundell+ (2013), Nature

Earliest afterglow is generally strongly polarized?

— No.

- Summary and Future Prospects

# Summary of Kanata telescope

- Originally constructed for multi-wavelength observation
- Basic, multi-purpose instruments have been developed and are always stand-by for observation
- Unique results have been provided for optical/NIR photometry/polarimetry monitoring for Blazars, XBs, GRBs, supernovae, etc.

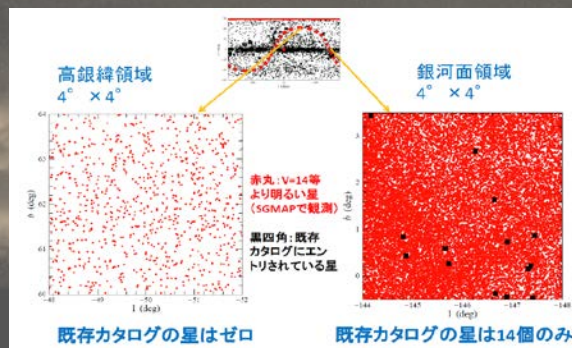

# Future Prospects with Kanata telescope

- Collaborative Study with future telescopes/satellites  
(Small telescopes still can contribute featuring unique modes.)

- Search and Follow-up of Optical Counterpart of Gravitational Wave Source (a member of J-GEM)
- Promoting a future project: SGMAP  
First polarimetric survey in northern hemisphere

$\sim 10^4$  stars (existing catalogue)

$\rightarrow 10^6 - 10^7$  stars

Supplementary with Gaia astrometry  
(including distance) catalogue ( $\sim 2021$ )

**➔ Seeds for future study**
